MICROPROCESSOR WITH PROTECTION CIRCUITS TO SECURE THE ACCESS TO ITS REGISTERS

Abstract of the Disclosure

A microprocessor is provided with protection circuits to secure access to its registers. The microprocessor includes a plurality of protection circuits, each associated with a register of the 5 microprocessor. The protection circuits automatically block selection of the registers after each resetting of the microprocessor. The releasing of a protection circuit associated with a register is done by the successive sending, on the data bus, of N passwords 10 proper to the register during N first operations for the selection of the register with N≥1. The selection of the register is effective only for the subsequent operations for selection of the register up to the next resetting of the microprocessor.
